Abstract

The genus Phytophthora causes great damages to agricultural production, especially to potatoes and tomatoes cultures. To face these losses, it is of interest to reduce or inhibit the activity of this aggressive pathogen. Some species of Trichoderma have great potential for the biological control of several plant pathogens, including diseases caused by Phytophthora parasitica, Rhizoctonia solani, Pythium ultimum, Fusarium oxysporum, Sclerotinia sclerotiorum etc. The purpose of this study was to assess the biocontrol efficacy of three Trichoderma strains (T. asperellum T36, T. asperellum T50, T. harzianum T78) against Phytophthora parasitica. In vitro tests were carried out using dual culture technique. In vivo tests were carried out with pepper seedlings (Capsicum annum cv. Lamuyo) and conidial standard suspension of Trichoderma isolates as biocontrol agents. Of the three Trichoderma isolates tested for their effectiveness against mycelial growth of pathogen, T. asperellum T36 (91.2%) exhibited maximum inhibition of P. parasitica, compared with the control, followed by T. asperellum T50 (79.6%) and T. harzianum T78 (77.7%). Likewise for the in vivo test, the inoculation of the Trichoderma biocontrol agent showed that the percentage of dead plants seedlings was significant reduced. T. asperellum T36 is a useful biological alternative to pesticides for the control of P. parasitica in pepper seedlings.

Key words: biocontrol, Phytophthora parasitica, Trichoderma.

INTRODUCTION

The genus Phytophthora is classified as oomycetes and is an important plants pathogen. Phytophthora spp. has a severe economic impact on agriculture, the induced economic losses being approximately 170 billion US dollars (Haverkort et al., 2009; Wu et al., 2012; Fatima et al., 2015). Phytophthora spp. grows through the root and the stem system of plant, destroying it by, causing root and stem rot. The plants diseases were primarily managed with fungicide applications but the phytopathogens haves developed resistance. For the management of fungal crop diseases another effective way is the biological control. Some microorganisms have the ability to antagonize pathogens (Fatima et al., 2015). The genus Trichoderma is known as a biocontrol agent (BCAs) and can suppress diseases via several mechanisms including antibiotic, competence, mycoparasitism, enzyme activity, induced plant defence, (Papavizas and Lumsden, 1980; Howell, 2003).

In this study we evaluated the biocontrol potential of three Trichoderma strains, T. asperellum T36, T. asperellum T50, T. harzianum T78 against Phytophthora parasitica.

MATERIALS AND METHODS

Fungal isolates
The fungal virulent pathogen Phytophthora parasitica belongs to Culture Collections of CEBAS-CSIC Institute, Murcia, Spain. The strain was isolated from pepper plants showing disease symptoms and was maintained on pea agar medium at 28°C for 7 days. The biological control agents (BCAs), Trichoderma asperellum T36, Trichoderma asperellum T50 belong to Culture Collections of ICECHIM Institute, Romania. Both strains were isolated from soil. Trichoderma harzianum T78 was obtained from Culture Collections of CEBAS-CSIC Institute.
The antagonistic strains were grown and maintained on potato dextrose agar medium (PDA) at 26 to 28°C for 7 days.

**Dual culture technique**

The antagonistic activity of *Trichoderma* strains against *P. parasitica* was evaluated by dual culture method described by Edington et al., 1971.

Plates of rye agar medium were inoculated with a 5 mm disc from five-day-old cultures of each *Trichoderma* strains which was placed 2 cm away from the periphery of the plate. Same size agar disc of *P. parasitica* was placed at the opposite side of *Trichoderma* sample, 2 cm away from the periphery of the plate. The control contains only the fungal phytopathogen. The cultures were incubated at 28 ºC in darkness. After 5 days of incubation the growth of the fungi was recorded by measuring the radial growth of the pathogens. The inhibition percentage was calculated in relation with the control by using the formula:

\[
I(\%) = \frac{(C-T)}{C} \times 100
\]

where,

- \( I \) = percent of inhibition
- \( C \) = diameter of radial growth of *P. parasitica* in control
- \( T \) = diameter of radial growth of *P. parasitica* in the presence of antagonistic strains.

**Greenhouse experiment**

In this study four treatments were formulated: T1 - compost, black peat and *T. harzianum* T78 (10⁶ ufc g⁻¹); T2 - compost, black peat and *T. asperellum* T36 (10⁶ ufc g⁻¹); T3 - Compost and black peat; T4 - Black peat.

Seeds of pepper (*Capsicum annuum* cv. Lamuyo) were sterilized in 10% NaClO for 3 minutes and rinsed for three times in sterile water. The pepper seeds were planted in 150 pots, with one seed per pot (Figure 1).

For each treatment forty-eight pots were used: 18 pots were used as control (without pathogen) and thirty pots were inoculated with *P. parasitica*. All plants were incubated in growth chamber under daylight conditions. After 14 days of sowing the seedlings were inoculated with *P. parasitica* (10⁵ ufc g⁻¹, in all treatments). The seedlings were harvested four weeks after sowing. The number of infected plants was recorded every day.

**RESULTS AND DISCUSSIONS**

**In vitro growth inhibition of *P. parasitica* by *Trichoderma* strains**

The antagonism of *Trichoderma strains* against *P. parasitica* was observed in dual culture. Figure 2 and Table 1 show the inhibition of *P. parasitica* by the *Trichoderma* strains. The results of dual culture demonstrated that *T. asperellum* T36 determined the maximum growth inhibition of *P. parasitica* (81.2%), followed by *T. asperellum* T50 (79.6%) and *T. harzianum* T78 (77.7%) (Table 1).

Inhibition of *Phytophthora* growth by *Trichoderma* spp. was also reported previously by (Fatima et al., 2015; Jiang et al., 2016).

**Greenhouse trial**

The results of the greenhouse experiment showed that the inoculation of *Trichoderma* strains in the growing media was an effective treatment to control *P. parasitica* in pepper seedlings.

Figure 3 demonstrated that the treatment T2 (fortified with *T. asperellum* T36) showed the lowest percentage of dead pepper seedlings induced by *P. parasitica* (54%), followed by treatment T1, T3 and T4 (66%, 80% and 92.66%, respectively).
The antagonistic strains were grown and maintained on potato dextrose agar medium (PDA) at 26 to 28°C for 7 days.

Dual culture technique

The antagonistic activity of Trichoderma strains against P. parasitica was evaluated by dual culture method described by Edington et al., 1971. Plates of rye agar medium were inoculated with a 5 mm disc from five-day-old cultures of each Trichoderma strains which was placed 2 cm away from the periphery of the plate. Same size agar disc of P. parasitica was placed at the opposite side of Trichoderma sample, 2 cm away from the periphery of the plate. The control contains only the fungal phytopathogen. The cultures were incubated at 28 ºC in darkness. After 5 days of incubation the growth of the fungi was recorded by measuring the radial growth of the pathogens. The inhibition percentage was calculated in relation with the control by using the formula:

\[ I(\%) = \frac{(C-T)}{C} \times 100 \]

where,

- \( I \) = percent of inhibition
- \( C \) = diameter of radial growth of P. parasitica in control
- \( T \) = diameter of radial growth of P. parasitica in the presence of antagonistic strains.

Greenhouse experiment

In this study four treatments were formulated:

Inhibition of Phytophthora growth by Trichoderma spp. was also reported previously by (Fatima et al., 2015; Jiang et al., 2016).

Greenhouse trial

The results of the greenhouse experiment showed that the inoculation of Trichoderma strains in the growing media was an effective treatment to control P. parasitica in pepper seedlings. Figure 3 demonstrated that the treatment T2 (fortified with T. asperellum T36) showed the lowest percentage of dead pepper seedlings induced by P. parasitica (54%), followed by treatment T1, T3 and T4 (66%, 80% and 92.66%, respectively).

Figure 2. Antagonistic test between Trichoderma strains and Phytophthora parasitica
T. asperellum T36 (treatment T2) was more effective than T. harzianum T78 (treatment T1) in reducing the percentage of dead pepper seedlings.

Similar results were reported previously by (Mpika et al., 2009; Segarra et al., 2013). Figure 4 shows the survival of a pepper seedling after harvesting (a) and a dead pepper seedling with stem rot (b).

**CONCLUSIONS**

All three isolates of Trichoderma demonstrated biological control activity against P. parasitica. In the growth chamber experiment, the disease severity was reduced by T. asperellum T36 and T. harzianum T78. Treatment T2 with T. asperellum T36 was the most effective treatment to control P. parasitica in pepper seedlings.
